## Introduction

OCCQP, written in the MATLAB ${ }^{\circledR}$ programming language, uses quadratic programming (QP) to optimize site occupancies in crystals; Wright et al. (2000) provide details of the problem and the nomenclature used in this manual. All site assignments are based on x-ray structural and chemical data.

This manual has two parts: the first section explains the basic use of OccQP, and the second section details how the user generates output files, bypasses stored constants, and tests the viability of any site assignment.

## Basic Use

Input files. Each separate problem will have its own input file defining the following objects: having these variables defined:

```
Name = 'Optional reference information';
Atoms ={ 'Atomic species' };
Cobs =[ Chemical content in atoms per unit cell ];
Sites ={ 'Site names' };
Qobs =[ Electron population of each site ];
C =[ Rank of each site ];
Coord =[ Coordination number of each site ];
dA ={ Bond length 'Anion' };
```

The Name variable is optional, but all others are essential. Input files must be flat text files (i.e., with no word-processor formatting) with names of the form "filename.m". Such files can be created with the MATLAB ${ }^{\circledR}$ text editor: start the MATLAB environment
(e.g., double-click on the MATLAB icon) and select the "File $\Rightarrow$ New $\Rightarrow$ M-file" pulldown menu item. Type in the input data (see the example below) and save the file with the desired filename.

Example 1. Dravite, Hawthorne et al. (1993). In this example we examine how four atomic species $[\mathrm{Al}, \mathrm{Fe}(\mathrm{III}), \mathrm{Fe}(\mathrm{II}), \mathrm{Mg}]$ distribute between the $Y$ and $Z$ sites of a dravite tourmaline. First we create the input file "drav1.m":

```
Name ='Dravite Tourmaline (Hawthorne et al., 1993, ..
    AM 78,265)';
Atoms ={ 'Al' 'Fe(III)' 'Fe(II)' 'Mg' };
Cobs =[ll.075 0.560 0.051 2.211 ];
Sites ={ 'Y' 'Z' };
Qobs =[[ 15.15 13.03 ];
C =[ 3 6 ];
Coord =[[ 6 6 ];
% Anything to the right of '%' is a comment.
% d anion
dA={ 1.953 'O' % begin site Y
    2.002 '0'
    2.002 'O'
    2.117 'O'
    1.989 'O'
    1.989 '0'
    2.002 'O' % begin site Z
    1.915 'O'
    1.960 'O'
    1.908 'O'
    1.931 '0'
    1.900 'O' };
```

Atomic species have single quotes around them, and must be one of the species listed in Appendix 1. The observed chemistries, Cobs, must be in the same order as Atoms. Similar to Atoms, entries in Sites must have single quotes around them. The electron populations, Qobs, the site rank $C$, and coordination number, Coord, must be listed in the same order as Sites. The array of bond lengths and atoms bonded to the sites, $d A$, must also be listed in that order. Finally, each array definition should end with a semicolon to suppress extraneous screen output of the array.

Running OCCQP. To run OCCQP, start MATLAB ${ }^{\circledR}$ and make sure the file "occqp.m" is in the MATLAB search path. In the example below, this is accomplished by moving into the directory C: $\backslash$ Matlab\Research containing "occqp.m". Next call OccQP by entering its name at the MATLAB command line:

```
>> cd c:\matlab\research
>> occqp
```

This command brings up a selection menu:

To select the previously created dravite input file (see p. 4), double-click on "drav1.m" to display the default site assignments:

| Eile |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  | Chemistry |  |
| Solve | Y | z | Calc'd | Observed |
| AI | 0.3688 | 0.8313 | 6.0945 | 6.0750 |
| Fe(III) | 0.1984 | 0.0000 | 0.5951 | 0.5600 |
| Fe[ll] | 0.0000 | 0.0139 | 0.0835 | 0.0510 |
| Mg | 0.4328 | 0.1543 | 2.2245 | 2.2110 |
| Vacancy | 0.0000 | 0.0004 | 0.0024 | 0.1030 |
| Charge | -0.0042 | -0.0087 | $\begin{array}{ll} \hline \text { O } & \text { Set Gioals } \\ \text { C } & \text { Occupancy by Site } \\ \text { O } & \text { Occupancy by Atom } \end{array}$ |  |
| Valence | -0.0101 | -0.0195 |  |  |
| Length | 0.0033 | 0.0044 |  |  |

The default optimum occupancies are calculated using unit weights on chemistry, charge, valence, and average bond length. Choose Occupancy by Atom to show how each atom is apportioned among the sites:

| - Dravite Tourmaline [Hawthorne et al., 1993,... - - $^{\text {a }}$ |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| File |  |  |  |  |
| Solve |  |  | Chemistry |  |
|  | Y | z | Calc'd | Observed |
| Al | 0.1816 | 0.8184 | 6.0945 | 6.0750 |
| Fe[III) | 1.0000 | 0.0000 | 0.5951 | 0.5600 |
| Fe[II] | 0.0000 | 1.0000 | 0.0835 | 0.0510 |
| Mg | 0.5837 | 0.4163 | 2.2245 | 2.2110 |
| Vacancy | 0.0000 | 1.0000 | 0.0024 | 0.1030 |
| Charge | -0.0042 | -0.0087 | $\begin{array}{ll} \hline \mathrm{C} & \text { Set Goals } \\ \mathrm{C} & \text { Occupancy by Site } \\ \text { C } & \text { Occupancy by Atom } \end{array}$ |  |
| Valence | -0.0101 | -0.0195 |  |  |
| Length | 0.0033 | 0.0044 |  |  |

The weights and goals (click the Set Goals toggle) are the defaults (unit weight, all atomic species are allowed into either site, and vacancies are allowed):

| Eile |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  | Chemistry |  |
| Solve | Y | z | Calc'd | Observed |
| Al | variable | variable | 1.0000 | 6.0750 |
| Fe(III) | variable | variable | 1.0000 | 0.5600 |
| Fe(II] | variable | variable | 1.0000 | 0.0510 |
| Mg | variable | variable | 1.0000 | 2.2110 |
| Vacancy | variable | variable | 0.0000 | 0.1030 |
| Charge | 1.0000 | 1.0000 | $C$ Set Goals <br> C Occupancy by Site <br> C Occupancy by Atom |  |
| Valence | 1.0000 | 1.0000 |  |  |
| Length | 1.0000 | 1.0000 |  |  |

Output residuals. The observed chemistry is simply the Cobs array specified in the input file. The observed vacancy is the difference between the sum of ranks and the sum of chemistries:

$$
\text { observed vacancies }=\sum_{j}^{m} C^{(j)}-\sum_{k}^{n} C_{k}^{o b s} .
$$

See Wright et al. (2000) for nomenclature. This value could be negative, meaning that (according to the chemistry) there are more atoms than available sites. The values labeled Charge, Valence, and Length are the following residuals for each site j:

$$
\begin{aligned}
& \sum_{k}^{n} x_{k}^{(j)} Q_{k}-Q_{o b s}^{(j)}, \\
& \sum_{k=1}^{n} x_{k}^{(j)} Z_{k}-\sum_{k=1}^{n} x_{k}^{(j)} V_{k}^{(j)}, \\
& \sum_{k=1}^{n} x_{k}^{(j)} D_{k}^{(j)}-\sum_{k=1}^{n} x_{k}^{(j)} \hat{d}^{(j)} .
\end{aligned}
$$

## Advanced Use

For this section we use the same dravite, but consider five cation sites (X, Y, Z, T, and B) and all twelve atomic species. Make the following ".m" file, calling it "drav2.m"; note that to continue long lines of input simply use ellipses (...):

```
Name ='Dravite Tourmaline (Hawthorne et al., 1993,..
    AM 78,265)';
Atoms = {'Al' 'Ti(IV)' 'Cr(III)' 'Fe(III)'...
        'Fe(II)' 'Mg' 'Mn(II)' 'Ca'...
        'Na' 'K' 'Si' 'B'};
Cobs = [ 6.075 0.030 0.006 0.560\ldots
        0.051 2.211 0.003 0.009...
        0.814 0.014 6.080 3];
\begin{tabular}{|c|c|c|c|c|c|c|}
\hline Sites \(=\) \{ & 'X' & 'Y' & 'Z' & 'T' & 'B' & \} \\
\hline Qobs = [ & 9.27 & 15.15 & 13.03 & 0 & 0 & ]; \\
\hline \(\mathrm{C}=\) [ & 1 & 3 & 6 & 6 & 3 & ]; \\
\hline Coord \(=\) [ & 9 & 6 & 6 & 4 & 3 & ]; \\
\hline
\end{tabular}
dA={ { 2.5040 'O' 
```

Start OccQP and select "drav2.m". The default weighting will give meaningless results because no values were reported for Qobs at the T and B sites. Therefore, select Set Goals and change the default weights on the Charge residuals to zero for these sites. This is accomplished by double-clicking on the desired entries and typing ' 0 '.

| - Dravite Tourmaline (Hawthorne et al., 1993, AM 78,265) |  |  |  |  |  | - - |  |

Testing other site assignments. OccQP can be used to determine residuals in published site-assignments. Simply double-click on any occupancy box in the output, and input the desired value. The residuals are recalculated using the input site occupancies. In the example below, the site assignments made by Hawthorne et al.
(1993) are input and the residuals calculated:

| 4 Dravite Tourmaline [Hawthorne et al., 1993, AM 78,265] |  |  |  |  |  |  | - $\square^{\text {a }}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| Length | -0.0598 | 0.0094 | 0.0006 | 0.0035 | -0.0028 |  |  |

Changing Weights. By changing weights, OccQP can perform site assignment calculations wherein the user makes judgements on the validity of each observation. In addition, site assignments can be input by the user. In the example below we fix all the Si in the T site, and all the B in the B site, as suggested by crystal chemical intuition. Infinite weights (inf) are placed on the chemistry equations in order to honor the analyzed chemistry exactly in the optimization.

(Optimal solution using weights shown in the preceding figure.)

The <File> menu. Load and Reload. Load works identically to the command
"occqp" from the MatLab ${ }^{\circledR}$ screen. Using Reload restarts the current file. This command is useful when the program "hangs up" or fails.

Save and Save As. These commands provide a quick way of recording the weighting scheme and constraints used for a calculation, as well as the results of an optimization. A saved file also contains the values used for $Q, Z$, and $R$, allowing the user to change these values.

Chemical aggregation. The optional variable Caggr allows grouping of two or more species into one "aggregated" species, such as aggregating $\mathrm{Fe}(\mathrm{II})$ and $\mathrm{Fe}(\mathrm{III})$ as total Fe . When the Caggr line is added to the input file, atoms with like values of Caggr will be constrained to the total value of Cobs, but the optimization process will apportion the atoms between the species to minimize residuals. For example, with addition of the Caggr line to the input below,

| Atoms $=\left\{{ }^{\prime} \mathrm{Na}{ }^{\prime}\right.$ | 'K' | 'Ca' | 'Al' | 'Mg' | 'Fe(II)' | '(III) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $\mathbf{Q}=$ [ 11 | 19 | 20 | 13 | 12 | 26 | 26 ]; |
| $\mathrm{Z}=$ [ 1 | 1 | 2 | 3 | 2 | 2 | 3 ]; |
| Cobs $=$ [ 0.814 | 0.014 | 0.009 | 6.075 | 2.211 | 0.051 | 0.56 |
| Caggr $=[1$ | 2 | 3 | 4 | 5 | 6 | 6 |

the amount of Fe (II) and $\mathrm{Fe}(\mathrm{III})$ will be varied, with the Cobs goal of 0.611 total Fe atoms. Such a utility is useful when total Fe is analyzed but no oxidation data are available: Fe will be apportioned between the two valences to best meet the goals.

## Tips \& Trouble Shooting

Making new input files. The most frequent problem in building new input files is naming the atoms incorrectly. Atomic symbols must be enclosed between single quotes, and atoms with more than one possible valence state must have the valence expressed as a Roman numeral enclosed in parentheses. Allowed atom nomenclature is given in the Appendix 1.

It is not necessary to end each line with a semicolon (;), but doing so reduces extraneous output to the screen.

## Appendix 1

Values of Q, Z, and R as stored in QccQP.m. R values from Brese and O'Keeffe (1991).

| Cation | $Q$ | Z | $\boldsymbol{R}(0)$ | $\boldsymbol{R}(\boldsymbol{F})$ | $\boldsymbol{R}(\mathrm{Cl})$ | $\boldsymbol{R}(\mathbf{S})$ |

## System Requirements, Program Availability

OccQP is copyrighted software. It is available free of charge and can be obtained from this web site or directly from the authors. Version 0.39 of OccQP consists of a single Matlab ${ }^{\circledR}$ M-file "occqp.m" which must be run within the Matlab computing environment in conjunction with the MatLab Optimization Toolbox. Version 0.39 was written using MATLAB version 5.2 and works with MATLAB versions 5.2 and 5.3 on a Windows95 platform. MATLAB ${ }^{\circledR}$ and its Optimization Toolbox are commercial software products which can be purchased from The MathWorks, Inc., 24 Prime Park Way, Natick, MA 01760-1500.
